Abstract
Dental caries can be caused by *Streptococcus mutans* bacteria. *Robusta* coffee bean extract has an inhibitory effect on the growth of *Streptococcus mutans* bacteria. Compounds that have antibacterial activity are chlorogenic acid (CGA), caffeine, caffeic acid and trigonelline. *Robusta* coffee bean extract has the potential to be formulated into mouthwash. This study aims to make a mouthwash formula with the active ingredient of roasted *Robusta* coffee extract and then evaluate the preparation and test its effectiveness against *S. mutans* bacteria. Mouthwash preparations were made in 3 formulas with different glycerin concentrations, namely 5%, 10%, and 15%. The stability test of the preparation used the treatment before and after the forced condition. Bacterial inhibition test using agar diffusion method with the positive control, namely commercial mouthwash Chlorhexidine and negative control mouthwash formula without extract content. Data analysis used the Kruskal-Wallis test to determine the differences in each treatment, and the Mann-Whitney test to see which treatment groups were significantly different. The results of the evaluation of the stability of the preparation showed that the three formulations of the mouthwash of roasted *Robusta* coffee bean extract had organoleptic stability, pH, and viscosity. The results of the inhibitory effectiveness test showed that the mouthwash formulation of formula 1 produced an inhibition zone of 1.6 mm, formula 2 of 2.1 mm, formula 3 of 2.4 mm, positive control of 6.8 mm, and negative control did not produce obstacles zone. It can be concluded that the three mouthwash formulas have antibacterial activity in the weak category (<5 mm). The concentration of glycerin in the formula had no significant effect on the stability of the preparation and the antibacterial effectiveness of *S. mutans*. The results of the inhibitory effectiveness test showed that the mouthwash formulation of formula 1 produced an inhibition zone of 1.6 mm, formula 2 of 2.1 mm, formula 3 of 2.4 mm, positive control of 6.8 mm, and negative

**Keywords:** Robusta coffee (Coffea canephora); the bacteria S. mutans; mouthwash formulations; antibacterial.

**INTRODUCTION**

Coffee is one of the fruits that is processed into drinks and is often consumed by the people of Indonesia. One type of coffee that is in great demand is Robusta coffee. Robusta coffee (Coffea canephora) is widely grown in Africa, India, and Indonesia. Robusta coffee commodity in Indonesia is very high so that it can dominate the national market, but only controls 30% of the world market compared to Arabica coffee which is 70% (Tanauma et al., 2016). Robusta coffee production centers in Central Java are in Temanggung Regency (30.27%), Semarang and Salatiga (10.86%), Kendal (8.69), Jepara (7.67%), and Wonosobo (6.06%) (Oelviani, 2017).

Chemical content in robusta coffee beans is alkaloid compounds, tannins, saponins, and polyphenols (Chairgulprasert, 2017). Caffeine is one of the most important alkaloid compounds in coffee beans which can inhibit bacterial growth. The caffeine content in robusta coffee beans is around 1.6%-2.4% (Tanauma et al., 2016). In addition to caffeine, another important compound is polyphenol compounds. The most abundant polyphenolic compounds in coffee are chlorogenic acid and caffeic acid. The amount of chlorogenic acid reaches 90% of the total phenol found in coffee (Yusmarini, 2011). The content of chlorogenic acid in coffee beans is about 8% or 4.5% in roasted coffee. During roasting, most of the chlorogenic acid becomes caffeic acid and quinic acid (Yusianto and Dwi, 2014).

The results of Yaqin and Nurmilawati (2015) research on the effect of robusta coffee extract (Coffea canephora) as an inhibitor of the growth of Staphylococcus aureus bacteria showed that robusta coffee extract could inhibit Staphylococcus aureus with a minimum concentration of 12.5% and the most effective inhibitory power was a concentration of 100 %. Another study conducted by Chamidah (2012), stated that robusta coffee bean extract has antibacterial power against the growth of Porphyromonas gingivalis at concentrations of 100%, 50%, and 25%. Compounds that have antibacterial activity are chlorogenic acid (CGA), caffeine, caffeic acid, and trigonelline (Siebert et al., 2018). Apart from being antibacterial, robusta coffee extract also has antioxidant and anti-inflammatory activity (Almeida et al., 2012).

Robusta coffee bean ethanol extract also has an inhibitory power against bacteria that cause dental plaque, namely Streptococcus mutans starting at a concentration of
1.56%, (Maheswari et al., 2015). Streptococcus mutans is a cariogenic bacteria because it is able to stick to the tooth surface (Rahman et al., 2017) and is a bacterium that often causes dental caries (Dewi et al., 2015). Prevention efforts need to be made to control caries risk factors. One of the efforts to control the causes of dental caries is the use of antibacterial mouthwash. The use of commercial antibacterials turns out to have some side effects such as changes in normal flora and resistance of microorganisms in the oral cavity (Rahman et al., 2017). This prompted researchers to formulate mouthwash with active ingredients derived from herbal ingredients, namely ethanol extract of roasted robusta coffee beans. Many types of research on the activity of robusta coffee bean extract have been carried out, but there is still little research on the activity in the dosage form, especially as an antibacterial for the oral cavity. In addition, many factors influence the occurrence of differences in chemical components in robusta coffee bean extract, namely the heating or roasting of green coffee beans or also called "roasted coffee", genetic factors, cultivars, cultivation processing practices by farmers, climate, soil type, and the environment. around (Farah et al., 2012). Differences in these components will affect the level of activity. Therefore, the researcher intends to determine the activity of robusta coffee bean extract in the form of mouthwash preparations. The robusta coffee bean extract used comes from local farmers in the Wonosobo area, Central Java, where the coffee has been heated or roasted (roasted coffee).

METHOD

The tools used in this research are rotary evaporator (Bio Base), autoclave (Model YXQ.SG41.46.280AS), measuring pipette (pyrex), ose, micropipette (Dragon Onemed), Bunsen, analytical balance (ACIS), caliper, laminar flow (WINA Type 304), incubator (WINA Type 801), cup (Normax), Ostwald viscometer, and glassware.

The materials used in this study were ethanol extract of roasted robusta coffee beans, xylitol (Brataco), glycerin (Brataco), sodium benzoate, methylparaben, propylparaben, aqua dest, ethanol, disc, Streptococcus mutans bacteria obtained from the Pro Technology Laboratory, Nutrien Agar (Merch), Nutrien Broth (Merch), and Muller Hinton Agar (Merch).

This type of research is the experimental laboratory. The research design used was a post-test-only control group design. The sample used in this study is roasted robusta coffee beans (Coffea canephora) which are sold in Kepil District, Wonosobo Regency.

The samples obtained were macerated with 96% ethanol. The resulting extract was subjected to phytochemical screening. Then a mouthwash was formulated with ingredients, namely 6% roasted robusta coffee bean extract, xylitol, glycerin, sodium benzoate, methylparaben, propylparaben, and aqua dest. Made in 3 formulas with different concentrations of glycerin, namely 5%, 10%, and 15%. The mouthwash formula made was evaluated for preparations including organoleptic, pH, and viscosity tests under conditions before and after conditions were imposed. After evaluating the preparation, the mouthwash formula was tested for effectiveness on S. mutans bacteria. The following is the procedure for testing the antibacterial effectiveness of roasted robusta coffee bean mouthwash preparations.
Preparation of Nutrient Agar (NA) Lean Media and Inoculation of S. mutans.

Bacteria

A total of 2.8 g of NA was put into an Erlenmeyer and added 100 mL of sterile distilled water. Heated on the stove until homogeneous. Covered with cotton and then sterilized for 15 minutes in an autoclave at 121ºC. Pour 5 mL into a sterile test tube. The media is placed with the desired slope and wait for it to harden. The bacteria obtained from the Pro Technology Laboratory were tightly etched on the media so that it tilted in a zigzag fashion from bottom to top. Then the cultures were incubated at room temperature (37ºC) for 24 hours (Mahmudah and Atun, 2017).

Preparation of Liquid Media and Suspension of S. mutans

Liquid medium was prepared from Nutrient broth (NB). Weighing 3.25 g of NB was put into an Erlenmeyer, added 250 mL of distilled water. The media is heated on an electric stove and stirred until it boils and is homogeneous. The homogeneous media was poured into 50 mL Erlenmeyer as much as 30 mL NB. Sterilized using autoclave for 15 minutes at a temperature of 121ºC. The media was allowed to stand for 24 hours.

Planting of bacteria in liquid media is done by taking one colony of bacteria on slanted agar media that has been grown previously using a sterile ose needle, then inserted into the liquid medium. Bacteria in liquid media were then incubated for 24 hours at 37º C. The growth of S. mutans was indicated by the presence of turbidity in the media (Maheasy and Atun, 2017).

Production of Muller Hinton Agar (MHA) Media

Weigh 38 g of MHA media, then add 1000 mL of distilled water. The MHA medium was stirred and heated using a hot plate. The MHA media was sterilized by autoclave for 15 minutes at a temperature of 121º C. Then the media was poured into sterile Petri dishes as much as 15 mL and the work was carried out in the LAF (Maheasy and Atun, 2017).

Inhibitory Test Phase

Streptococcus mutans inhibition test was assessed using the agar diffusion method. This research was conducted using 3 empty plates and 15 discs. The disc paper was soaked for 5 minutes in each formula and control.

a. Formula 1, mouthwash with 5% glycerin concentration
b. Formula 2, mouthwash with 10% glycerin concentration
c. Formula 3, mouthwash with 15% glycerin concentration
d. Control (+), mouthwash Minosep® (Chlorhexidine)
e. Control (-), mouthwash formula that does not contain roasted robusta coffee bean extract.

In each petri dish containing MHA medium 0.1 mL of Streptococcus mutans suspension was inoculated, then 5 paper Blancs were placed from 5 different treatments. Do 3 repetitions. Incubated for 24 hours at 37ºC. After 24 hours, the Petri dishes were removed from the incubator and then the clear zone or zone of inhibition seen on each disc was measured using a caliper. Measurements were carried out 3 times by different people who previously had equalized perceptions and taken the average (Maheasy and Atun, 2017). If the inhibition zone is oval, then measurements are made on the long
diameter (eg an mm) and the short diameter (eg b mm) then both are added and divided by two. So the diameter of the inhibition zone \(x = (a+b)/2\).

The research data were tested for normality with the Kolmogorov Smirnov test and homogeneity test with the Levene Test. If both tests show normal and homogeneous data \((p> 0.05)\), then a parametric statistical test is carried out, namely One Way Anova. However, if the data is not normally distributed and/or not homogeneous, it is continued with a nonparametric statistical test, namely Kruskal Wallis.

**RESULTS AND DISCUSSION**

**Making Roasted Robusta Coffee Bean Ethanol Extract**

The extraction of roasted robusta coffee beans produces an extract with the characteristics of a thick blackish-brown liquid, and has a distinctive aroma of roasted coffee. The thick extract obtained after concentration was 9.68 g with a yield of 4.84%. The yield obtained is slightly lower when compared to previous research conducted by Kiatissin et al (2016), the yield obtained from the maceration of roasted robusta coffee beans is 5.43%. The difference in the yield value can be caused by several factors including the size of the simplicia, the extraction time, and the concentration of the solvent used (Juliantari et al., 2018). The results of phytochemical screening showed that the ethanol extract of roasted robusta coffee beans was positive for alkaloids, flavonoids, tannins, and saponins. This is following previous research conducted by Utami et al, (2018).

**Roasted Robusta Coffee Bean Extract Mouthwash Formulation**

The preparation of ethanol extract mouthwash preparations of roasted robusta coffee beans is based on the formulation in the research of Gowatham et al, (2020). Making mouthwash requires ingredients, namely thick roasted robusta coffee bean extract, xylitol, glycerin, sodium benzoate, methylparaben, propylparaben, and aqua dest. The use of roasted robusta coffee bean extract as an antibacterial active ingredient. The use of xylitol as a sweetener. The use of sodium benzoate, methylparaben, and propylparaben, as preservatives. The use of aqua dest as a solvent. The use of glycerin in the formulation is to increase the solubility of the extract which is not completely soluble in water. Humectants such as glycerin are used 5-20% in mouthwash to give a certain sensation in the mouth.

Mouthwash contains the active ingredient of roasted robusta coffee bean extract by 6% because it is based on previous research by Maheswari et al, (2015).Robusta coffee bean extract was able to inhibit the growth of S. mutans bacteria starting from a concentration of 1.56%. Mouthwash preparations were made in three formulas with varying concentrations of glycerin, namely 5%, 10%, and 15%. Variations in glycerin concentration were carried out to determine the effect of humectants on the stability of the mouthwash and its inhibition against S. mutans bacteria.

**Mouthwash Stability Test**

The mouthwash stability test was carried out with forced treatment conditions, namely storage at a temperature of 5ºC and 35ºC for 12 hours each for 10 cycles (Ririn et al., 2013). The following are the results of the stability test for mouthwash preparations:

**a. Organoleptic Examination Results**

Organoleptic examination of mouthwash preparations includes the examination of color, odor, and taste. These parameters are visual characteristics and physical characteristics that can be observed directly (Handayani et al., 2017). The results of organoleptic observations are based on table 2, namely, the three formulas have the same odor and color, have a distinctive coffee odor, and are brown. This is because all mouthwash formulas contain an active ingredient, namely ethanol extract of roasted robusta coffee beans with the same concentration. The mouthwash taste of the three formulas has the same taste, which is freshly sweet. The sweet taste is because the mouthwash contains a sweetener, namely xylitol and the fresh taste is due to the glycerin content which gives a certain sensation in the mouth (Suryani et al., 2019). There was no difference in sweet taste in the three formulas because the added concentration of xylitol sweetener was the same. The difference in the concentration of glycerin in each mouthwash formula did not result in a difference in the taste and sensation of the mouthwash in the mouth.

The results of organoleptic examination after accelerated storage did not change the smell, color, and taste of the mouthwash. This is because mouthwash contains preservatives, namely sodium benzoate, methylparaben, and propylparaben. Preservatives function to maintain the stability of the mouthwash in storage.

**b. pH test**

The pH value is very influential on the type of bacteria that can grow in a preparation. Most bacteria have an optimum pH value of around 6.5-7.5 (Lukas, 2012). Therefore, the mouthwash preparation that is made must be outside the pH value range. Based on table 2 the pH value obtained in each formula is 5. The value obtained is by the pH of the mouthwash according to Hidayanto et al., (2017) which ranges from 5-7, besides that the pH obtained is outside the optimum pH range for bacterial growth. The results showed that the pH of the mouthwash preparation did not change after the condition was forced. This indicates that the mouthwash formula has good pH stability.
c. Viscosity Examination Results

The viscosity of the mouthwash formulation greatly affects the level of viscosity of the mouthwash when used to gargle in the mouth. The closer the viscosity level of the mouthwash formulation to the viscosity of water, the more comfortable and easy it is to use in the mouth. The viscosity of pure water is 1002 Pa.s or approx \( \pm 0.010 \) P (Luke, 2012).

The results of the viscosity analysis on each mouthwash formula showed that the viscosity value of the formula ranged from 0.0104-0.0158 P. The viscosity value of the mouthwash formula before and after the forced condition was formula 1 (0.0109; 0.0104)P, formula 2 (0.0142;0.0130)P, and formula 3 (0.0158;0.0146)P. The highest viscosity value is shown by formula 3 with the largest glycerin concentration of 15%, while the lowest viscosity occurs in formula 1 with the smallest glycerin concentration of 5%. The difference in viscosity values is caused by differences in the glycerin content in the formula. Based on the literature, glycerin has a viscosity value of 0.0114 P at a concentration of 5% and 0.0131 P at a concentration of 10% (Yosephine et al., 2013). The greater the glycerin content in the preparation, the greater the viscosity value of the preparation (Baitariza et al., 2020). Although the viscosity value obtained is greater than the viscosity value of water, it still meets the viscosity standard for commercial mouthwash preparations, which is 0.0725 P (Noval et al., 2020).

The results of the viscosity measurement before and after the forced condition decreased the viscosity value in each preparation. The difference in storage temperature when conditions are forced results in a decrease in the viscosity of the preparation. The viscosity of the preparation will vary depending on the temperature, generally, the viscosity of the liquid decreases with increasing temperature (Ririn et al., 2013). The decrease in the value of the viscosity of the mouthwash after forced storage was also due to the solution form having a relatively shorter storage period when compared to the solid dosage form. This happens because the preparation in the form of a solution is easily decomposed by temperature and light, besides that it can react with the environment (Handayani et al., 2016). Although the value of the viscosity of the mouthwash formula decreased. However, statistically, there was no significant difference (\( \alpha > 0.05 \)) between before and after the condition was imposed on all mouthwash formulas. It can be concluded that the three formulations of roasted robusta coffee bean ethanol extract mouthwash have storage stability.

Effectiveness Test of Roasted Robusta Coffee Bean Extract Mouthwash (Coffea canephora) Against S. mutans Bacteria

The effectiveness test of the ethanol extract of roasted robusta coffee bean mouthwash formula against S. mutans bacteria was carried out using the agar diffusion method. The measurement results showed that all mouthwash formulas had an antibacterial activity with a weak category (diameter <5 mm).(Handayani et al., 2017). The following are the results of the inhibition zone measurements formed from each formula and control in millimeters (mm):

**Table 3. Results of Inhibitory Effectiveness Test Against S. mutans bacteria**

The data in table 3. then tested for normality with Shapiro-Wilk. The significance value obtained is less than 0.05, so it can be concluded that the data are not normally distributed. After the data is said to be not normally distributed, a non-parametric alternative test is conducted in the form of the Kruskal Wallis test. The results of the Kruskal Wallis test can be seen in the following table:

Table 4. shows the values obtained <0.05, meaning that the inhibition of S. mutans in the control group and the treatment group had a significant difference. To find out which treatment groups were significantly different, further tests were carried out with Mann Whitney.

The results of the Mann-Whitney test in table 5. show that there is a significant difference between the negative control and the mouthwash formula, both formulas 1, 2, and 3. It can be seen that there are also significant differences between the positive control and the mouthwash formula, both formula 1, 2, and 3, but also significantly different from the negative control. No significant difference was found in each mouthwash formula.

The antibacterial test was carried out using the agar diffusion method. The clear zone formed around the disc proved that the mouthwash formula of roasted robusta coffee bean extract had antibacterial activity against S. mutans. Based on table 3. above, it can be seen that the three mouthwash formulas can inhibit the growth of S. mutans bacteria with different diameters. The greater the glycerin content in the mouthwash formula, the greater the inhibitory power. This is because glycerin is a humectant function to increase the contact time of the mouthwash formula with bacteria. In addition, glycerin also helps to maintain the evaporation of excess water in the preparation (Anastasia et al., 2017). However, statistical analysis showed that there was no significant difference ($\alpha>0.05$) between formula 1, formula 2, and formula 3. So it can be concluded that the variation of glycerin has no significant effect on the antibacterial effectiveness of mouthwash. There is an assumption that the greater the glycerin content in the formula, the better the antibacterial effectiveness. This assumption does not apply in this study. This can happen because according to Rowe et al (2009), in HPE page 301, the working activity of glycerin can be reduced if there is an interaction with phenol/polyphenol compounds in inappropriate concentrations. This assumption does not apply in this study. This can happen because according to Rowe et al (2009), in HPE page 301, the working activity of glycerin can be reduced if there is an interaction with phenol/polyphenol compounds in inappropriate concentrations. This assumption does not apply in this study. This can happen because according to Rowe et al (2009), in HPE page 301, the working activity of glycerin can be reduced if there is an interaction with phenol/polyphenol compounds in inappropriate concentrations.

According to Handayani et al., (2017), The antibacterial inhibition was divided into very strong (clear zone >20 mm), strong (10-20 mm clear zone), moderate (5-10 mm clear zone), and weak (clear zone <5 mm). Based on the research that has been done, formula 1 produces an inhibition zone of 1.6 mm, formula 2 produces an inhibition zone of 2.1 mm, formula 3 produces an inhibition zone of 2.4 mm so that the inhibitory ability produced by the three ethanol extract mouthwash formulas Roasted robusta coffee beans can be categorized as weak. The negative control used did not produce inhibition against S. mutans. The positive control showed the presence of antibacterial activity against S. mutans with an inhibition zone diameter of 6.8 mm in the medium category.

There are differences in the results of the effectiveness of the inhibitory power of chlorhexidine positive control against S. mutans bacteria with previous studies conducted by Sinaredi et al. (2014), in his research chlorhexidine had an inhibitory power of 16 mm with a strong category. Another study conducted by Suryani et al. (2014) also resulted in different inhibitory effectiveness, which was 29.1 mm in the very strong category. The difference in effectiveness could be caused by, among others, the difference in the number of colonies of S. mutans bacteria because in this study there was no comparison of bacterial suspension with Mc Farland standards, and mutations or bacterial contamination occurred during storage, causing resistance to antibacterial compounds.

Previous research conducted by Maheswari et al, (2015) investigated the inhibitory power of robusta coffee bean extract on the growth of S. mutans bacteria. It is stated that robusta coffee bean extract can inhibit the growth of S. mutans bacteria starting from a concentration of 1.56%. This is in line with the research conducted, namely the formulation of mouthwash of roasted robusta coffee bean extract with a concentration of 6% can inhibit the growth of S. mutans bacteria with a weak category.
Chemical compounds contained in the ethanol extract of roasted robusta coffee beans that act as antibacterial are caffeine, chlorogenic acid (CGA), caffeic acid, and trigonelline (Siebert et al., 2018). Caffeine is an alkaloid compound. The content of alkaloids in the ethanol extract of roasted robusta coffee beans has the antibacterial ability because it has a quaternary aromatic group capable of intercalating with DNA, alkaloids also interfere with the integrity of the peptidoglycan constituent components in bacterial cells (Rahman et al., 2017).

Chlorogenic acid and trigonelline are compounds of the flavonoid group. Flavonoid compounds are antibacterial through 3 mechanisms, namely: inhibiting nucleic acid synthesis, inhibiting cell membrane function, and inhibiting energy metabolism (Rahman et al., 2017). Brooks et al (2010) stated that the structure of the bacterial cell wall also plays a role in determining the binding, penetration, and activity of an antibacterial compound.

The content of other compounds in roasted robusta coffee bean extract that has antibacterial activity is saponins and tannins. Saponins work effectively on gram-positive bacteria such as S. mutans. The antibacterial action mechanism of saponins is by increasing the permeability of the cell membrane so that the membrane becomes unstable and results in cell hemolysis (Dewi et al., 2015). The content of tannin compounds in the ethanol extract of roasted robusta coffee beans has antibacterial action related to its ability to deactivate bacterial adhesion, inhibit enzyme activity, and inhibit protein transport in the cell envelope. The mechanism of action of tannins as antibacterial agents is through the destruction of bacterial cell membranes due to tannin toxicity and the formation of metal ion complex bonds from tannins which play a role in tannin toxicity (Rahman et al., 2017). According to Xie et al, (2008) tannins have the effect of inhibiting the growth of S. mutans bacteria.

The results of statistical analysis showed that the data obtained were not normally distributed. The analysis was continued with a non-parametric test, namely Kruskal-Wallis, and obtained a significance value of <0.05, meaning that the inhibitory power of S. mutans in each treatment group had a significant difference. The results of the Mann-Whitney test in table 5. show that there is a significant difference between the mouthwash formula and the negative control. This indicates that the mouthwash formula has antibacterial activity against S. mutans. The effectiveness of mouthwash was smaller when compared to the positive control. It can be seen that there is a significant difference between the mouthwash formula and the positive control in the test.

The results of the measurement of the diameter of the inhibition zone showed that the higher the glycerin content in the mouthwash formula, the greater the antibacterial effectiveness against S. mutans. But statistically, it can be concluded that the variation of glycerin has no significant effect on the antibacterial effectiveness of mouthwash. Variations in glycerin also did not significantly affect the stability of mouthwash preparations. So that the best mouthwash formula used is mouthwash formula 1 with 5% glycerin content which has a viscosity value closest to the viscosity of water. The closer the viscosity level of the mouthwash formulation to the viscosity of water, the more comfortable and easy it is to use in the mouth (Lukas, 2012).
CONCLUSIONS

Conclusion

Based on the results of the research that has been done, the following conclusions can be drawn:

a. The three formulations of roasted robusta coffee bean ethanol extract mouthwash with variations of glycerin 5%, 10%, and 15% had pH, organoleptic, and viscosity stability. The results of statistical analysis showed that the viscosity of the three mouthwash formulas did not have a significant difference before and after the forced condition.

b. The three formulas of mouthwash of roasted robusta coffee bean extract had antibacterial activity against S. mutans with a weak category (diameter <5 mm). The results of statistical analysis showed that variations in glycerin had no significant effect on the antibacterial effectiveness of mouthwash.

Suggestion

Suggestions from this research include:

a. Further research needs to be done using positive control in the form of herbal mouthwash to compare the antibacterial effectiveness between mouthwash and herbal active ingredients.

b. It is necessary to research the activity of mouthwash against other bacteria that cause dental caries.
